Motivations, common interest Applied, Materials Science

In nanotechnologies large areas of **nanopatterns** are needed, which can be fabricated today only by expensive techniques, e.g. : electron beam lithography or direct writing with electron and ion beams.

Silicon Nanowire Diameter <100nm

65 billion nanodots per square cm

Top-down versus Bottom-up technologies

Similar results can be obtained through bottom-up and top-down processes

Roadmap of Top-down and Bottom-Up Processing

http://www.imec.be/wwwinter/business/nanotechnology.pdf

Fundamental theoretical understanding of the ion-beaminduced surface patterning and scaling is needed ! Kardar-Parisi-Zhang (KPZ) equation $\partial_{t}h(x,t) = \sigma \nabla^{2}h(x,t) + \lambda (\nabla h(x,t))^{2} + \eta(x,t)$

- *σ* : (smoothing) surface tension coefficient
- λ : anisotropy, local growth velocity
- η : roughens the surface by a zero-average Gaussian noise field:

$$\langle \boldsymbol{\eta}(x,t)\boldsymbol{\eta}(x',t')\rangle = 2 D \delta^d (x-x')(t-t')$$

Up-down symmetrical case: \lambda = 0 : Edwards-Wilkinson (EW) equation

Characterization of surface growth:

Width:

$$W(L,t) = \left[\frac{1}{L^2} \sum_{i,j}^{L} h_{i,j}^2(t) - \left(\frac{1}{L} \sum_{i,j}^{L} h_{i,j}(t)\right)^2\right]^{1/2}$$

Family-Vicsek scaling:

 $\begin{aligned} W(L,t) &\propto t^{\beta}, & \text{for } t_0 << t << t_s \\ &\propto L^{\alpha}, & \text{for } t >> t_s \;. \end{aligned}$

KPZ phase diagram, scaling classes

• Exactly solvable in 1+1 d, but in higher dimensions theory fails being unable to access the strong coupling fixed point regime

FIG. 1. Schematic phase diagram of the KPZ equation from the one-loop RG analysis. Transitions are marked by thick lines.

Table	7.2	Scaling	expo-
nents	of KF	PZ classe	8.

d	$\tilde{\alpha}$	β	Z
1	1/2	1/3	3/2
2	0.38	0.24	1.58
3	0.30	0.18	1.66

• The upper critical dimension is still debated: $d_{2} = 2, 4, \dots \infty$?

• 2-dim exponent estimates : $\alpha = 0.36 - 0.4$

Mappings of KPZ onto lattice gas system in 1d

Mapping of the 1+1d surface growth onto the 1d **ASEP** model

Attachment (with prob. *p*) and Detachment (with prob. *q*) -> Anisotropic diffusion of particles (bullets) along the 1d base space (*M. Plischke*, *Rácz and Liu, PRB 35, 3485 (1987)*)

'Kawasaki' exchange of particles

The simple **ASEP** (Ligget '95) is an exactly solved lattice gas

Many features (response to disorder, different boundary conditions ...) are known.

Applications of ASEP

Microtubule

ASEP = "Ising" model of nonequilibrium physics

since it is simple, exactly solvable, and has many applications as follows:

- Protein synthesis
 - Surface growth
 - Boundary induced phase transitions
 - Real and/or Model Traffic
 - Intracellular Transport
 - Ant Trails

Test of parallel update algorithms for 1d ASEP/KPZ

• Parallel updates on a ring of size L:

Odd timesteps

Even timesteps update

with probability *p* (reverse with *q*)

- Scaling by the serial C and CUDA: Agreement with 1d KPZ scaling
- L<16K programs fits into shared memory of multiprocessor blocks
 → no communication losses, maximal speedup & scaling:
 240 cores ~ 100x of a CPU (2GHz)

Further Motivations, non-trivial problem Disordered ASEP

Bidirectional two-lane model

- single particle, homogeneous system: active diffusion (Klumpp & Lipowsky 2005)
- single particle in random environment
- many-particle system is qualitatively different from the disordered PASEP

Exploration of exremely slow (scaling) behavior: Fits GPUs

Mappings of KPZ growth in 2+1 dimensions

FIG. 2: (Color online) Mapping of the 2 + 1 dimensional surface growth onto the 2d particle model (bullets). Surface attachment (with probability p) and detachment (with probability q) corresponds to Kawasaki exchanges of particles, or to anisotropic diffusion of dimers in the bisectrix direction of the x and y axes. The crossing points of dashed lines show the base sub-lattice to be updated. Thick solid/dashed lines on the surface show the x/y cross-sections, corresponding to the 1d model (Fig. 1.)

 $W^{2}(t) = 0.152 \ln(t) + b \text{ for } t < t_{st}$ $W^{2}(L) = 0.304 \ln(L) + d \text{ for } t > t_{st}$ Generalized Kawasaki update:

$$\begin{pmatrix} -1 & 1 \\ -1 & 1 \end{pmatrix} \rightleftharpoons \begin{pmatrix} 1 & -1 \\ 1 & -1 \end{pmatrix}$$

Octahedron model Driven diffusive gas of pairs (dimers) G. Ódor, B. Liedke and K.-H. Heinig, PRE79, 021125 (2009)

First 2-dim KPZ CUDA implementation on byte-fields (dimers)

H. Schulz, G.Ó, Jeffrey Kelling, Karl-Heinz Heinig, Bartosz Liedke, Nils Schmeißer Proceedings of the 3rd International Workshop "Innovation in Information Technologies -Theory and Practice", September 6th-10th, Dresden, Germany, 2010

Prospects: KPZ in higher dimensions

Generalization of the rooftop (octahedron) model in higher (d=3,4,5) dimensions (64⁵ sized lattices!)

In *d* dimensions: $KPZ \sim$ spatially anisotropic, driven random walk of oriented *d*-mers \Rightarrow Topological exclusion effects make them nontrivial

 Upper-critical dimension: Irrelevancy of topological constraints above a finite d_c?

G.Ó, B.L, K.H: PRE81 (2010) 031112

Pattern formation with the octahedron model

Competing KPZ and surface diffusion :

Noisy **Kuramoto-Sivashinsky** equation (KPZ + Mullins Diffusion):

 $\partial_t h(x,t) = \sigma \nabla^2 h(x,t) + \lambda (\nabla h(x,t))^2 + \eta(x,t) + k \nabla^4 h(x,t)$ To generate patterns inverse (uphill) diffusion is needed !

Alternating deposition/removal (prob. p,q) and surface diffusion (prob. D)

Scaling behavior of the 2d Kuramoto-Sivashinsky ~ KPZ ??? debated Field Theoretical hypothesis 1995 (Howard & Cuerno)

Surface diffusion (Molecular Beam Epitaxy classes)

dimer attraction

Simultaneous octahedron deposition/removal: attracting or repelling dimers G.Ó, et al. PRE81 (2010) 051114

Curvature driven octahedron model
$$\land$$

 $\lor \lor \lor \lor \lor$
Arrhenious type update probability

$$c_{\chi}(i,j) = \sigma_{\chi}(i,j)\sigma_{\chi}(i+1,j)$$
$$\Delta H = \Delta \sum_{\chi=x,y} \sum_{\langle i,j \rangle} c_{\chi}(i,j) + \Delta \sum_{\chi=x,y} \sum_{\langle i',j' \rangle} c_{\chi}(i',j')$$
$$w_{i \to i'} = 1/2[1 - a \tanh(-\Delta H^2)]$$

Surface hight patterns generated by the dimers

Anisotropic surface diffusion

Silicon surface after 500 eV Ar+ sputtering under 67°. The ripples have a periodicity of 35 nm and a height of 2nm.

Coarsening ripples periodicity Wavelength growth (scaling) ?

Patterns generated

Isotropic surface diffusion

1KMCS

10KMCS

Experiment

Coarsening dots

GaSb surface after normal 500 eV Ar+ sputtering. The periodicity and the height of the dots are both 30 nm.

CUDA code implementation

Important issues:

- CUDA code runs faster than C by a factor \Leftrightarrow programming effort ?
- Fit into shared GPU memory to reduce communication losses
- Bit coding
- Smaller sizes, Finite Size Scaling (FSS) studies
- Good/fast random number generator selection

Project works for 2010-2011

 Local Supercomputer thanks to NVIDIA professor partnership:
