Quark matter near T_c

RHIC \Rightarrow matter near T_c almost perfect fluid, $\eta/s \lesssim 0.1$

Hard to describe theoretically

- non-interacting particles form a **free gas**: free mean path is infinite \Rightarrow transport coefficients are **infinite** (eg. η)
- in **weakly interacting gas** $\eta \sim 1/\sigma$ (cross section)
 $\sim 1/g^4 \times \text{logs} \Rightarrow \eta$ **still large**
- for small η we need large coupling constant
 \Rightarrow non-perturbative system
- **small η** \Rightarrow small mean free path \Rightarrow fast decay
 \Rightarrow for elementary excitations: width \sim mass
 \Rightarrow **unstable quasiparticles** (unparticles?)

MC studies

In principle exact method to measure η/s ...

- measure $\langle T_{12}(\mathbf{x}) T_{12}(0) \rangle$ correlator on lattice \Rightarrow Euclidean discrete time
- we need the spectral function, which is related to the correlator as

$$\int d^3\mathbf{x} \langle T_{12}(\tau, \mathbf{x}) T_{12}(0) \rangle = \int_0^\infty \frac{d\omega}{\pi} C(\omega, \mathbf{k} = 0) \frac{\cosh(\omega(\beta/2 - \tau))}{\sinh \beta\tau/2}.$$
- invert this relation with the prior knowledge $C(\omega > 0) > 0$
Maximal Entropy Method, or ad hoc solutions
- too little sensitivity to small ω regime \Rightarrow large systematical uncertainties; additional assumptions are needed
- best estimates $\eta/s = 0.102(56)$ at $T = 1.24 T_c$

(H. B. Meyer, Phys. Rev. D 76, 101701 (2007))

\Rightarrow needs analytic control!

Conformal approach

Strongly interacting systems with large symmetry group (conformal symmetry) can be analytically treated: instead QCD we use $\mathcal{N} = 4$ SYM theory

- spectral functions are continuous
- duality, strongly interacting CFT can be mapped to weakly interacting gravity systems.
- in $N_c \gg 1$ and $\lambda = g^2 N_c \gg 1$ limit classical gravity can be used

But this method also has disadvantages

- QCD is not conformally symmetric
- at finite N_c and λ string corrections can be relevant.

We need generic statements about systems with large-width excitations

eta/s in different systems

- transport coefficients: diffusion constants of conserved quantities \Rightarrow linear response theory should be used

$$C(x) = \langle [J_i(x), J_i(0)] \rangle \Rightarrow D = \lim_{\omega \rightarrow 0} \frac{C(\mathbf{k} = 0, \omega)}{\omega}$$

for the shear viscosity $J_i \rightarrow T_{12}$

- in the perturbative regime Boltzmann equations or microcanonical approach can be used
- order of magnitude from Navier-Stokes equation: $\rho \dot{v} \sim \eta \Delta v$
 $\Rightarrow \eta \sim \rho v^2 \tau \sim \epsilon \tau$

(τ lifetime, ℓ mean free path, v velocity, ϵ energy density)

$$\text{and } s \sim n \text{ (particle density)} \Rightarrow \frac{\eta}{s} \sim E \tau$$

 - Lower bound for η/s
- 2 eta/s in field theory
 - Transport coefficients
 - Entropy density
- 3 Model calculations
 - Small width case
 - Broad spectral function
 - System with zero mass excitations
- 4 Conclusions

- argumentation: $\eta \sim \epsilon\tau$, $s \sim n \Rightarrow \frac{\eta}{s} \sim E\tau$

$$\text{In quasiparticle systems } E > \Delta E \Rightarrow \frac{\eta}{s} \gtrsim \Delta E\tau \gtrsim \hbar$$

P. Danielewicz, M. Gyulassy, PRD 31, 53 (1985); P. Kovtun, D.T. Son, A.O. Starinets PRL 94, 111601 (2005).

- calculation: for $\mathcal{N} = 4$ SYM theory at $N_c \gg 1$, $\lambda = g^2 N_c \gg 1$ from graviton absorption in the dual 5D AdS gravity:

$$\frac{\eta}{s} = \frac{1}{4\pi}$$

(P. Kovtun, D.T. Son, A.O. Starinets JHEP 0310, (2003) 064.)

- for weaker coupling we expect larger ratio: indeed, first λ , N_c corrections are positive (R.C. Myers, M.F. Paulos, A. Sinha, arXiv:0806.2156)
- universal for a wide class of theories (A. Buchel, R.C. Myers, M.F. Paulos, A. Sinha, Phys.Lett.B669:364-370,2008.; M. Haack, A. Yarom, arXiv:0811.1794)
- so far we did not find counterexamples experimentally

Theoretical caveats

- $\mathcal{N} = 4$ SYM theory is not QCD
 - $1/4\pi$ limit is not stable against higher curvature/dilaton corrections.
 - Counterexample: N species with the same interaction $\Rightarrow \eta$ is not changed, $s \sim \ln N$ (mixing entropy) $\Rightarrow \frac{\eta}{s} \sim \frac{1}{\ln N}$
- (A. Cherman, T. D. Cohen, and P. M. Hohler, JHEP 02, 026 (2008), 0708.4201.)
- in QFT there is always a continuum – effect on η/s ?

pure hadron gas vs. hadron gas with continuum \Rightarrow considerable difference

(J. Noronha-Hostler, J. Noronha and C. Greiner, PRL 103, 172302 (2009), 0811.1571)

RHIC data

Non-central heavy ion collisions have initial anisotropy.
 Time evolution of anisotropy: the larger the viscosity, the more
 extent the initial anisotropy is washed out

(P. Romatschke, U. Romatschke, *Phys.Rev.Lett.*99:172301,2007.)

upper bound: $\frac{\eta}{s} \lesssim 0.16 \Rightarrow$ is there a lower bound?

Lower bound for η/s RHIC data vs. $1/4\pi$ 

P. Romatschke, U. Romatschke, PRL.99:172301,2007.

R.A. Lacey, A. Taranenko, R. Wei, arXiv:0905.4368

- Quadratic correction in p_T is expected (D.A. Teaney, arXiv:0905.2433)
- Statistically $\frac{\eta}{s} < \frac{1}{4\pi}$ is not excluded (favored: $\left. \frac{\eta}{s} \right|_{\langle p_T \rangle=0} \approx 0.9 \pm 0.07$)

RHIC seriously challenges the conjectured lower bound!

Idea: if we knew the exact energy levels

- ⇒ calculate (or learn something about) η/s
- ⇒ generic statements (e.g. for lower bound)
- ⇒ effect of continuous spectrum.

QM-based description:

$$\sum_n |n\rangle \langle n| = V \sum_Q \int \frac{d^4 p}{(2\pi)^4} \varrho_Q(p) |p, Q\rangle \langle p, Q| \equiv \int_Q |p, Q\rangle \langle p, Q|,$$

where ϱ is the spectral function (density of states, DoS), Q denotes conserved quantities (quantum channel), $p = (p_0, \mathbf{p})$ is the total energy-momentum of the state.

- use volume normalization to calculate densities
- DoS can depend on the temperature.

$C_J(x) = \langle [J_i(x), J_i(0)] \rangle \Rightarrow \eta_J = \lim_{\omega \rightarrow 0} C_J(\omega)/\omega$
 generic transport coefficient.

- insert complete basis of energy-momentum eigenstates

$$C_J(x) = \frac{1}{Z} \sum_{n,m} \left[\langle n | e^{-\beta H} J(x) | m \rangle \langle m | J(0) | n \rangle - \{x \leftrightarrow 0\} \right]$$

- translation:

$$J(x) = e^{iP_x} A(0) e^{-iP_x} \Rightarrow \langle n | J(x) | m \rangle = e^{i(P_n - P_m)x} \langle n | J(0) | m \rangle$$

- Fourier transformation, $p = (p_0, \mathbf{p})$

$$C_J(p) = \frac{1}{Z} \sum_{n,m} (e^{-\beta E_n} - e^{-\beta E_m}) (2\pi)^4 \delta(p + P_n - P_m) |\langle m | J(0) | n \rangle|^2$$

- introduce spectral densities

$$\eta_J = \beta \frac{V^2}{\mathcal{Z}} \sum_{\mathcal{Q}} \int \frac{d^4 k}{(2\pi)^4} \varrho_{\mathcal{Q}}^2(k) e^{-\beta k_0} |\langle k, \mathcal{Q} | J_i | k, \mathcal{Q} \rangle|^2.$$

- current matrix element: $\langle k, \mathcal{Q} | J_i | k, \mathcal{Q} \rangle = \mathcal{J}_{\mathcal{Q}}(k) \frac{k_i}{V k_0}$
 - $\sim k_i/k_0 \sim v_i$ since J_i is a current
 - in free case $\mathcal{J}_{\mathcal{Q}}(k)$ is the charge carried by the current: for electric current $\mathcal{J} = e$ charge, for viscosity $\mathcal{J} \sim k_j$ momentum
 - in nonperturbative case $\mathcal{J}_{\mathcal{Q}}(k)$ can be momentum dependent.
- angular averaging

Finally:

$$\eta_J = \beta \frac{1}{3\mathcal{Z}} \sum_{\mathcal{Q}} \int \frac{d^4 k}{(2\pi)^4} \frac{\mathbf{k}^2}{k_0^2} e^{-\beta k_0} (\mathcal{J}_{\mathcal{Q}}(k) \varrho_{\mathcal{Q}}(k))^2.$$

Outlines

- 1 Introduction
 - Transport in plasma
 - Lower bound for η/s
- 2 eta/s in field theory
 - Transport coefficients
 - Entropy density
- 3 Model calculations
 - Small width case
 - Broad spectral function
 - System with zero mass excitations
- 4 Conclusions

$$\text{free energy density } \mathcal{Z} = e^{-\beta F} = \text{Tr} e^{-\beta H} = V \sum_{\mathcal{K}} \int \frac{d^4 k}{(2\pi)^4} \varrho_{\mathcal{K}}(k) e^{-\beta k_0}$$

Volume dependence of the free energy:

- for small sizes it is arbitrary
- as $V \rightarrow \infty$ we recover linear volume dependence
- crossover at scale L
 - volume elements larger than L interact weakly (surface interaction)
 - coarse graining scale \Rightarrow free energy density can be defined at scales larger than L
 - L is also an effective IR cutoff for the interactions.

\Rightarrow we choose a volume $V = L^3$ to define free energy density:

$$f = -\frac{T}{L^3} \ln \left(1 + L^3 \sum_{\mathcal{K}} \int \frac{d^4 k}{(2\pi)^4} \varrho_{\mathcal{K}}(k) e^{-\beta k_0} \right).$$

The eta/s ratio

with $s = -\frac{\partial f}{\partial T}$ and with angular averaging

$$\frac{\eta}{s} = \frac{\frac{\beta}{3\mathcal{Z}} \sum_{\mathcal{K}} \int \frac{d^4 k}{(2\pi)^4} \frac{\mathbf{k}^2}{k_0^2} e^{-\beta k_0} (\mathcal{J}_{\mathcal{K}}(k) \varrho_{\mathcal{K}}(k))^2}{-\frac{\partial}{\partial T} \frac{T}{L^3} \ln \left(1 + L^3 \sum_{\mathcal{K}} \int \frac{d^4 k}{(2\pi)^4} \varrho_{\mathcal{K}}(k) e^{-\beta k_0} \right)}.$$

Is there a lower bound in this formula?

Generic structure

Structure of η/s for small ϱ is

$$\frac{\eta_J}{s} \sim \frac{\int f_1 \varrho^2}{\int f_2 \varrho} \xrightarrow{\text{rescaling}} \frac{\langle \varrho^2 \rangle}{\langle \varrho \rangle}.$$

$\langle \varrho^2 \rangle \geq \langle \varrho \rangle^2 \Rightarrow$ we expect $\eta \gtrsim s^2$ up to rescaling factors.

Quasiparticle vs. non-quasiparticle systems:

- large peak in $\varrho \Rightarrow \varrho^2$ even larger $\Rightarrow \eta/s$ large
- ϱ small everywhere $\Rightarrow \varrho^2$ even smaller $\Rightarrow \eta/s$ small

in non-quasiparticle systems η/s is naturally small!

Lower bound – mathematical approach

More exactly:

- need a sum rule in each energy channel $\int \frac{dk_0}{2\pi} \varrho_Q(k_0) = U_Q$
- minimize η by tuning ϱ with respecting the sum rules and keeping the entropy density constant.
- technically: Lagrange multipliers
- two cases analytical: small/large s . The minimum values:

$$\frac{\eta}{s} \Big|_{min} \sim \frac{\mathcal{F}(L^3 s)}{N_Q (LT)^4}, \quad \mathcal{F} = \begin{cases} x & \text{for small } x \\ e^x/x & \text{for large } x \end{cases}$$

N_Q : number of effective quantum channels (species).

⇒ **There is a lower bound at finite s , but it is not universal.**

Simplifications

For the concrete model calculations we use simplifications

- We use generalized quasiparticle systems:

$$f = T \int \frac{d^4 k}{(2\pi)^4} \varrho_{QP}(k) (\mp) \ln \left(1 \pm e^{-\beta k_0} \right).$$

- we omit the effect of \mathcal{J}_Q and define a “reduced” viscosity coefficient as

$$\bar{\eta} = \frac{\beta}{15} \int \frac{d^4 k}{(2\pi)^4} \frac{(\mathbf{k}^2)^2}{k_0^2} e^{-\beta k_0} \varrho_{\mathcal{K}}^2(k).$$

Assume that the lowest lying states can be approximated with Breit-Wigner form

$$\varrho(q) = \frac{2\Gamma}{(q_0 - \varepsilon_q)^2 + \Gamma^2}.$$

In the small width limit $\varrho(q)^2 \approx \frac{2}{\Gamma} 2\pi\delta(q_0 - \varepsilon_q)$. As a consequence

$$\frac{\bar{\eta}}{s} = \frac{T}{\Gamma} f\left(\frac{m}{T}\right),$$

$f(m/T)$ depends on ε_k

if $\varepsilon_k = k$, $f = 540/\pi^4$ for bosons, $f = 4320/(7\pi^4)$ for fermions; if $\varepsilon_k = m + \frac{k^2}{2m}$, $f = 30\pi T/m, \dots$

- in conformal case $\Gamma \sim T \Rightarrow \eta/s \sim \text{constant}$
lower limit may come from infinite coupling, $1/4\pi$.
- massive case at low temperature: $\Gamma \sim e^{-M/T}$ (M : energy of scattering state) $\Rightarrow \eta/s \sim T e^{M/T} \xrightarrow{T \rightarrow 0} \infty$.

\Rightarrow in the small width quasiparticle case there is a lower bound

Outlines

- 1 Introduction
 - Transport in plasma
 - Lower bound for η/s
- 2 eta/s in field theory
 - Transport coefficients
 - Entropy density
- 3 **Model calculations**

For an opposite case consider a flat spectral function:

$$\varrho(k_0, k) = \frac{2\pi}{E_2 - E_1} \Theta(E_1 < k_0 < E_2)$$

step function, where $E_{1,2}(k) = \sqrt{k^2 + m_{1,2}^2}$. At small temperatures ($T < m_1$)

$$\frac{\eta}{s} = 6\pi \frac{T}{m_2 - m_1}$$

⇒ by broadening the distribution the viscosity to entropy density ratio has no lower bound

Outlines

- 1 Introduction
 - Transport in plasma
 - Lower bound for η/s
- 2 eta/s in field theory
 - Transport coefficients
 - Entropy density
- 3 Model calculations**
 - Small width case
 - Broad spectral function
 - System with zero mass excitations**

Zero mass excitations

- If there are in the system zero mass particles, then $m' = 0$
 \Rightarrow cut and the delta-peak melt together
- 1-loop threshold behavior **linear** $\Rightarrow \rho \sim 1/(E - E_{\text{thr}})$

Zero mass excitations

- If there are in the system zero mass particles, then $m' = 0$
 \Rightarrow cut and the delta-peak melt together
- 1-loop threshold behavior **linear** $\Rightarrow \rho \sim 1/(E - E_{\text{thr}})$

- This is not normalizable! \Rightarrow IR divergences near the threshold, which smear out the $1/x$ singularity

System with zero mass excitations

Zero mass excitations

- Interpretation: no single charged particle (electron, quark), it is always surrounded by soft gauge bosons

System with zero mass excitations

Zero mass excitations

- Interpretation: no single charged particle (electron, quark), it is always surrounded by soft gauge bosons
- In QCD: from fitting to MC pressure data one obtains similar distribution of quasiparticle masses

(T.S.Biro, P.Levai, P.Van, J.Zimanyi, Phys.Rev.C75:034910,2007)

The η/s ratio at low temperatures

$\varrho^\# e^{-\beta q_0}$ enhances the lowest lying states \Rightarrow power expand near the threshold:

$$\varrho(q) = \mathcal{C} q_0 \Theta(q - M)(q^2 - M^2)^w.$$

\mathcal{C} is dimensionfull: $[\mathcal{C}] = [E]^{-2(1+w)}$

$\eta_J \sim \mathcal{C}^2$ and $f \sim \mathcal{C} \Rightarrow \mathcal{C}$ remains in the ratio.

In the massive and massless case we find

$$\frac{\eta_J}{s} \sim \mathcal{C} M^w T^{2+w} \quad \text{and} \quad \mathcal{C} T^{2(1+w)} \xrightarrow{T \rightarrow 0} 0$$

for an integrable threshold ($w > -1$)

Outlines

 - Lower bound for η/s
- 2 eta/s in field theory
 - Transport coefficients
 - Entropy density
- 3 Model calculations
 - Small width case
 - Broad spectral function
 - System with zero mass excitations
- 4 Conclusions

Conclusions

- $1/4\pi$ lower bound for η/s is true only for quasiparticle and conformal theories
- in general the lower bound in a given environment depend on several factors; for small s

$$\frac{\eta}{s} \gtrsim \frac{s}{N_Q L T^4}$$

- model constructions with $\eta/s < 1/4\pi$:
 - step function spectral function
 - zero mass excitation with integrable threshold
- in QCD any of these effects can be important

Hydrodynamics

System with local collective flow: QM description?

Construction of the system: at $t = -\infty$ equilibrium in rest ($\bar{u} = (1, 0, 0, 0)$), then a modified time evolution corresponding to the flow u – denote $\Delta u = u - \bar{u}$:

$$H^{(0)} = \bar{u}_\mu P^{(0)\mu} = u_\mu P^\mu = H + \Delta u_\mu T^{0\mu} \quad \Rightarrow \quad \delta H = - \int d^3x \Delta u_\mu T^{0\mu}$$

$$\delta H = \int_{-\infty}^t dt' \partial_0 \delta H = - \int_{-\infty}^t dt' d^3x [\partial_0 u_\mu T^{0\mu} + \Delta u_\mu \partial_0 T^{0\mu}]$$

With energy-momentum conservation $\partial_0 T^{0\mu} = -\partial_i T^{i\mu}$ and partial integration

$$\delta H = - \int_{-\infty}^t dt' d^3x \partial_\mu u_\nu T^{\mu\nu}$$

- Linear response theory (\rightarrow the flowing and the original systems are not too far \Rightarrow nonrelativistic):

$$\delta \langle X(t) \rangle = i \int_{-\infty}^t dt' \int_{-\infty}^{t'} dt'' d^3 \mathbf{x}'' \langle [X(t), T^{\mu\nu}(\mathbf{x}'')] \rangle \partial_{\mu} u_{\nu}.$$

- Hydrodynamical approximation: $\partial u \approx \text{const.} \Rightarrow \delta \langle X \rangle$ time independent.

- spatial rotational symmetry of the ground state \Rightarrow

$$\delta \langle \pi_{ij} \rangle \equiv \delta \langle T_{ij} - \frac{1}{3} \delta_{ij} T_{.k}^k \rangle = \frac{\eta}{2} [\partial_k v_l + \partial_l v_k - \frac{2}{3} \delta_{kl} \partial v],$$

the coefficient from above (denote $C(x) = \langle [T_{12}(0), T_{12}(x)] \rangle$)

$$\eta = i \int_{-\infty}^0 dt \int_{-\infty}^t dt' d^3 \mathbf{x}' C(x') = \lim_{\omega \rightarrow 0} \frac{C(\omega, \mathbf{k} = 0)}{\omega}$$

Kubo formula

Zero temperature limit of viscosity

The viscosity η and the entropy have a common form

$$F_{n,m} = \frac{3a^5}{2\pi^3 T} \int \frac{d^4 k}{(2\pi)^4} \Theta(k_0) \Theta(k^2 - \sigma^2) e^{-k_0/T} (ak_0)^n \varrho^m(k),$$

since

$$\eta = N^2 \Delta^2 F_{0,2}, \quad s = 2F_{1,1}.$$

After reducing the integrals

$$a^3 F_{n,m} = C(a\sigma)^n (a^2 \sigma T)^{3/2} e^{-\sigma/T} \int_0^\infty dz e^{-z} \left(\frac{2(wz)^{5/2}}{1 + (wz)^5} \right)^m,$$

where $w = 2\Delta^{-2/5} T/\sigma$ rescaled temperature.

BOTH η and s goes to zero at zero temperature
